

## **Java Applet Programming Concepts(Part 2)**

For

**BCA 3<sup>rd</sup> Semester (Session 2017-20) Students (J.D. Women's College, Patna)**

By

**Sumit Kumar Verma**

## AWT

AWT stands for **Abstract Window Toolkit**. The Abstract Windowing Toolkit (AWT) is Java's platform-independent windowing, graphics, and user-interface widget toolkit. The AWT is part of the Java Foundation Classes (JFC) - the standard API for providing a graphical user interface (GUI) for a Java program.

### **Window Fundamentals**

The AWT defines windows according to a class hierarchy that adds functionality and specificity with each level. The two most common windows are those derived from panel, which is used by applets, and those derived from Frame, which creates a standard window.

### **Component**

At the top the AWT hierarchy is the **Component** class. **Component** is an abstract class that encapsulates all of the attributes of a visual component. All user interface elements that are displayed on the screen and that interact with the user are subclasses managing events, such as mouse and keyboard input, positioning and sizing the window, and repainting. A component object is responsible for remembering the current foreground and background colors and the currently selected text font.

### **Container**

The container class is a subclass of component. It has additional methods that allow other component objects to be nested within it. Other container objects can be stored inside of a **Container**. A **Container** is responsible for laying out (that is positioning) any components that it contains.

## Panel

The Panel class is a concrete subclass of Container. It doesn't add new methods; it simply implements Container.

## Window

The Window class creates a top-level window. A top-level window is not contained within any other object; it sits directly on the desktop. Generally, we won't create Window objects directly. Instead, we will use a subclass of Window called Frame.

## Frame

Frame encapsulates what is commonly thought of as a "window". It is a subclass of Window and has a title bar, menu bar, borders, and resizing corners. When a Frame window is created by a program rather than an applet, a normal window is created.

## Working with Frame Windows

After the applet, the type of window we will most often create is derived from Frame. We will use it to create child windows within applets, and top-level or child windows for applications.

There are two types of Frame constructors :

- a) **Frame()** -> It creates a standard window that does not contain a title.
- b) **Frame(String title)** -> It creates a window with the title specified by title. Here, we can't specify the dimensions of the window. Instead, we must set the size of the window after it has been created.

## Setting the window's Dimensions

- a) **setSize()** -> It is used to set the dimensions of the window.

Void setSize(int newWidth, int newHeight)

Void setSize(Dimension newSize)

The new size of the window is specified by newWidth and new Height, or by the width and height fields of the Dimension object passed in newSize. The dimensions are specified in terms of pixels.

## Hiding and Showing a window

After a frame window has been created, it will not be visible until you call setVisible().

void setVisible(boolean visibleflag)

The component is visible if the argument to this method is true. Otherwise, it is hidden.

## Setting a window's Title

We can change the title in a frame window using **setTitle()** method.

void setTitle(String newTitle)

Here, newTitle is the new title for the window.

## Closing a Frame window

When using a frame window, our program must remove that window from the screen when it is closed, by calling **setVisible(false)**. To intercept a window-close event, we must implement the **windowClosing()** method of the **WindowListener** interface.

## AWT Controls

Controls are components that allow a user to interact with your application and the AWT supports the following types of controls:

Labels, Push Buttons, Check Boxes, Choice Lists, Lists, Scrollbars, Text Components. These controls are subclasses of Component.

- 1) **Labels** : This is the simplest component of Java Abstract Window Toolkit. This component is generally used to show the text or string in your application and label never perform any type of action. Syntax for defining the label only and with justification :

```
Label label_name = new Label ("This is the label text.");
```

Above code simply represents the text for the label.

```
Label label_name = new Label ("This is the label text.", Label.CENTER);
```

Justification of label can be left, right or centered. Above declaration used the center justification of the label using the **Label.CENTER**.

- 2) **Buttons** : This is the component of Java Abstract Window Toolkit and is used to trigger actions and other events required for your application. The syntax of defining the button is as follows :

```
Button button_name = new Button ("This is the label of the button.");
```

we can change the Button's label or get the label's text by using the **Button.setLabel(String)** and **Button.getLabel()** method. Buttons are added to the it's container using the **add (button\_name)** method.

- 3) **Check Boxes** : This component of Java AWT allows you to create check boxes in your applications. The syntax of the definition of Checkbox is as follows :

```
Checkbox checkbox_name = new Checkbox ("Optional check box 1", false);
```

Above code constructs the unchecked Checkbox by passing the boolean valued argument *false* with the Checkbox label through the **Checkbox()** constructor. Defined Checkbox is added to it's container using **add (checkbox\_name)** method. we can change and get the checkbox's label using the **setLabel (String)** and **getLabel()** method. we can also set and get the state of the checkbox using the **setState(boolean)** and **getState()** method provided by the **Checkbox** class.

- 4) **Radio Button** : This is the special case of the Checkbox component of Java AWT package. This is used as a group of checkboxes which group name is same. Only one Checkbox from a Checkbox Group can be selected at a time. Syntax for creating radio buttons is as follows :

```
CheckboxGroup chkgp = new CheckboxGroup();
```

```
add (new Checkbox ("One", chkgp, false);
```

```
add (new Checkbox ("Two", chkgp, false);
```

```
add (new Checkbox ("Three",chkgp, false);
```

In the above code we are making three check boxes with the label "One", "Two" and "Three". If you mention more than one true valued for checkboxes then your program takes the last true and show the last check box as checked.

- 5) **Text Area**: This is the text container component of Java AWT package. The Text Area contains plain text. TextArea can be declared as follows:

```
TextArea txtArea_name = new TextArea();
```

we can make the Text Area editable or not using the `setEditable` (boolean) method. If you pass the boolean valued argument *false* then the text area will be non-editable otherwise it will be editable. The text area is by default in editable mode. Text are set in the text area using the `setText(string)` method of the **TextArea** class.

- 6) **Text Field**: This is also the text container component of Java AWT package. This component contains single line and limited text information. This is declared as follows :

```
TextField txtfield = new TextField(20);
```

You can fix the number of columns in the text field by specifying the number in the constructor. In the above code we have fixed the number of columns to 20.

### The Menu components

There are two types pop up and pull down. Pull down menus are accessed via a menu bar, which may contain multiple menus. Menu bars may appear only in frames.

To create a frame with a menu bar containing a pull down menu:

- Create a menu bar and attach it to frame.
- Create and populate the menu.
- Attach the menu to the menu bar.

To create a menu bar, instantiate `MenuBar` class. To attach it to frame, pass it into the frame's `setMenuBar()`.

To create a menu, instantiate `Menu` class. The most common constructor takes a string that is the menu's label. There are four kinds of elements that can be mixed and matched to populate a menu:

- **MenuItems**
  - A menu item is an ordinary textual component available on a menu. The basic constructor is *`MenuItem(String text)`* where *text* is the label of the menu item. A menu item is very much like a button that happens to live in a menu. Like buttons, menu items generate action events.
- **Checkbox MenuItems**
  - A checkbox menu item looks like a menu item with a checkbox to the left of its label. When a checkbox menu item is selected, the checkbox changes its state. The basic constructor is *`CheckboxMenuItem(String label)`*; You can read and set an item's state by calling `getState()` and `setState()`. These generate `ItemEvents`.
- **Separators**
  - A separator is just a horizontal mark used for visually dividing a menu into sections. To add a separator to a menu, call the menu's `addSeparator()` method().
- **Menus**
  - When you add a menu to another menu, the first menu's label appears in the second menu, with a pull-right icon. Pulling the mouse to the right causes the sub-menu to appear.

After a menu is fully populated, you attach it to a menu bar by calling menu bar's `add()` method. If you want the menu to appear in the Help menu position to the right of all other menus, call instead `setHelpMenu()`.

```

import java.applet.Applet;
import java.awt.Graphics;
import java.awt.*;
/*<applet code="AppletLifeCycle.class" width="350" height="150"> </applet>*/
public class AppletLifeCycle extends Applet
{
    public void init()
    {
        setBackground(Color.CYAN);
        System.out.println("init() called");
    }
    public void start()
    {
        System.out.println("Start() called");
    }
    public void paint(Graphics g){ System.out.println("Paint() called"); }
    public void stop() { System.out.println("Stop() Called"); }
    public void destroy() { System.out.println("Destroy() Called"); }
}

```

```
